GPA-package

GPA (Genetic analysis incorporating Pleiotropy and Annotation)

# **Description**

This package provides functions for fitting GPA, a statistical approach to prioritizing GWAS results by integrating pleiotropy information and annotation data, along with ShinyGPA, a visualization toolkit to investigate the pleiotropic architecture using GWAS results.

#### **Details**

Package: GPA
Type: Package
Version: 1.1.0
Date: 2017-06-30

License: GPL (>= 2)

LazyLoad: yes

This package contains a main class, GPA, which represents GPA model fit.

This package contains four main methods for the GPA framework (Chung et al., 2014), GPA, assoc, pTest, and aTest. GPA method fits the GPA model and assoc method implements association mapping. pTest and aTest methods implement hypothesis testing for pleiotropy and annotation enrichment, respectively.

This package contains two main methods for the ShinyGPA visualization toolkit (Kortemeier et al., 2017), fitAll and shinyGPA. fitAll function generates all the intermediate results needed to run shinyGPA opens the ShinyGPA interface, which takes the results generated from fitAll as input.

assoc

Association mapping

# **Description**

Association mapping.

assoc 5

#### Usage

```
assoc( object, ... )
## S4 method for signature 'GPA'
assoc( object, FDR=0.05, fdrControl="global", pattern=NULL )
```

#### **Arguments**

object GPA model fit.
FDR FDR level.

fdrControl Method to control FDR. Possible values are "global" (global FDR control) and

"local" (local FDR control). Default is "global".

pattern Pattern for association mapping. By default (i.e., pattern=NULL), assoc returns

a binary matrix indicating association of SNPs for each phenotypes. If a pattern is specified, a corresponding binary vector is provided. See the details about

how users can specify the pattern.

... Other parameters to be passed through to generic assoc.

#### **Details**

assoc uses the direct posterior probability approach of Newton et al. (2004) to control global FDR in association mapping.

Users can specify the pattern using 1 and \* in pattern argument, where 1 and \* indicate phenotypes of interest and phenotypes that are not of interest, respectively. For example, when there are three phenotypes, pattern="111" means a SNP associated with all of three phenotypes, while pattern="11\*" means a SNP associated with the first two phenotypes (i.e., association with the third phenotype is ignored (averaged out)).

#### Value

If pattern=NULL, returns a binary matrix indicating association of SNPs for each phenotype, where its rows and columns match those of input p-value matrix for function GPA. Otherwise, returns a binary vector indicating association of SNPs for the phenotype combination of interest.

```

aTest

Hypothesis testing for annotation enrichment

# **Description**

Hypothesis testing for annotation enrichment.

# Usage

```
aTest(fitWithoutAnn, fitWithAnn, vDigit=1000)
```

aTest 7

# **Arguments**

fitWithoutAnn GPA model fit without using annotation data. fitWithAnn GPA model fit with using annotation data.

vDigit Number of digits for reporting parameter estimates and standard errors. For

example, setting it to 1000 means printing out values up to three digits below

zero.

#### **Details**

aTest implements the hypothesis testing for annotation enrichment. It requires two GPA model fits, one fitted with using annotation data and one fitted without using annotation data, and evaluates annotation enrichment for risk-associated SNPs using the likelihood ratio test.

#### Value

Returns a list with components:

q q estimates.

statistics Statistics of the test for annotation enrichment.

p-value of the test for annotation enrichment.

fitAll

Fit GPA model for all possible pairs of GWAS datasets

# Description

Fit GPA model and the GPA model under H0 for all possible pairs of GWAS datasets.

# Usage

```
fitAll( pmat,
  maxIter=2000, stopping="relative", epsStopLL=1e-10,
  parallel=FALSE, nCore=8 )
```

# Arguments

pmat p-value matrix from GWAS data, where row and column correspond to SNP and

phenotype, respectively.

maxIter Maximum number of EM iteration. Default is 2000.

fitAll 9

stopping	Stopping rule for EM iteration. Possible values are "absolute" (based on absolute difference in log likelihood), "relative" (based on relative difference in log likelihood), or "aitken" (based on Aitken acceleration-based stopping rule). Default is "relative".
epsStopLL	Threshold to stop the EM iteration. Default is 1e-100.
parallel	Utilize multiple CPUs for parallel computing using "parallel" package? Possible values are TRUE (utilize multiple CPUs) or FALSE (do not utilize multiple CPUs). Default is FALSE (do not utilize multiple CPUs).
nCore	Number of CPUs when parallel computing is utilized.

# **Details**

fitAll function fits the GPA model and the GPA model under H0 for all possible pairs of GWAS datasets. Its output can be used as an input for the shinyGPA function.

# Value

A list with 6 elements, including pmat (original GWAS p-value matrix), combs (a matrix of GWAS pair indices), combList (a matrix of GWAS pair indices), pTestPval (a matrix of pleiotropy test p-values), fitGPA (a list of the GPA fit for each pair), and fitH0 (a list of the GPA fit under H0 for each pair).

```

GPA

Fit GPA model

# **Description**

Fit GPA model.

# Usage

```
GPA( gwasPval, annMat=NULL, pleiotropyH0=FALSE, empiricalNull=FALSE, maxIter=2000, stopping="relative", epsStopLL=1e-10, initBetaAlpha=0.1, initPi=0.1, initQ=0.75, lbPi=NA, lbBetaAlpha=0.001, lbQ=0.001, lbPval=1e-30, vDigit=1000, verbose=1)
```

# **Arguments**

gwasPval p-value matrix from GWAS data, where row and column correspond to SNP and

phenotype, respectively.

annMat Binary matrix from annotation data, where row and column correspond to SNP

and annotation, respectively.

GPA 11

pleiotropyH0 Fit GPA under the null hypothesis of pleiotropy test? Possible values are TRUE

(under the null hypothesis of pleiotropy test) or FALSE (usual assumption for

GPA). Default is FALSE.

empiricalNull Empirically estimate null distribution for GPA? Possible values are TRUE (empir-

ical null distribution) or FALSE (theoretical null distribution). Default is FALSE.

maxIter Maximum number of EM iteration. Default is 2000.

stopping Stopping rule for EM iteration. Possible values are "absolute" (based on ab-

solute difference in log likelihood), "relative" (based on relative difference in log likelihood), or "aitken" (based on Aitken acceleration-based stopping

rule). Default is "relative".

epsStopLL Threshold to stop the EM iteration. Default is 1e-100.

initBetaAlpha Initial value for alpha estimate. Default is 0.1.
initPi Initial value for pi estimate. Default is 0.1.
initQ Initial value for q estimate. Default is 0.75.

lbPi Lower bound for pi estimate. If lbPi=NA, lower bound is set to 1 / [number of

SNPs]. Default is NA.

lbBetaAlpha Lower bound for alpha estimate. Default is 0.001.lbQ Lower bound for q estimate. Default is 0.001.

lbPval Lower bound for GWAS p-value. Any GWAS p-values smaller than lbPval are

set to 1bPval. Default is 1e-30.

vDigit Number of digits for reporting parameter estimates. For example, setting it to

1000 means printing out values up to three digits below zero.

verbose Amount of progress report during the fitting procedure. Possible values are 0

(minimal output), 1, 2, or 3 (maximal output). Default is 1.

#### **Details**

GPA fits the GPA model. It requires to provide GWAS p-value to gwasPval, while users can also provide annotation data to annMat. It is assumed that number of rows of matrix provided to gwasPval equals to that provided to annMat.

pTest implements the hypothesis testing for pleiotropy. It requires two GPA model fits, one of interest and one under the null hypothesis, and they can be obtained by setting pleiotropyH0=FALSE and pleiotropyH0=TRUE, respectively.

aTest implements the hypothesis testing for annotation enrichment. It requires two GPA model fits, one fitted with using annotation data and one fitted without using annotation data, and they can be obtained by providing annotation data to annMat and not, respectively.

# Value

Construct GPA class object.

```

GPA-class 13

```
fit.GPA.pleiotropy.H0 <- GPA( pmat, NULL, pleiotropyH0=TRUE )</pre>
```

GPA-class

Class "GPA"

# Description

This class represents GPA model fit.

#### **Details**

When users use fdr method, users can specify the pattern using 1 and \* in pattern argument, where 1 and \* indicate phenotypes of interest and phenotypes that are not of interest, respectively. For example, when there are three phenotypes, pattern="111" means a SNP associated with all of three phenotypes, while pattern="11\*" means a SNP associated with the first two phenotypes (i.e., association with the third phenotype is ignored (averaged out)).

# **Objects from the Class**

Objects can be created by calls of the form new("GPA",...).

#### Slots

```
fit: Object of class "list", representing the fitted GPA model.
setting: Object of class "list", representing the setting for GPA model fitting.
gwasPval: Object of class "matrix", representing the p-value matrix from GWAS data.
annMat: Object of class "matrix", representing the annotation matrix.
```

#### Methods

```
show signature(object = "GPA"): provide brief summary of the object.
```

**print** signature(x = "GPA"): provide the matrix of posterior probability that a SNP belongs to each combination of association status.

fdr signature(object = "GPA", pattern=NULL): provide local FDR. By default (i.e., pattern=NULL), it returns a matrix of local FDR that a SNP is not associated with each phenotype (i.e., marginal FDR), where the order of columns is same as that in input GWAS data. If a pattern is specified, a vector of corresponding local FDR is provided. See the details about how users can specify the pattern.

cov signature(object = "GPA", silent=FALSE, vDigitEst=1000, vDigitSE=1000): provide the covariance matrix for parameter estimates of GPA model. If silent=TRUE, it suppresses the summary output. vDigitEst and vDigitSE control number of digits for reporting parameter estimates and standard errors. For example, setting it to 1000 means printing out values up to three digits below zero.

estimates signature(object = "GPA"): extract parameter estimates from GPA model fit.
se signature(object = "GPA"): extract standard errors for parameter estimates from GPA model
fit.

pTest

Hypothesis testing for pleiotropy

# Description

Hypothesis testing for pleiotropy.

# Usage

```
pTest( fit, fitH0, vDigit=1000 )
```

# **Arguments**

fit Fit of the GPA model of interest.

fitH0 GPA model fit under the null hypothesis of pleiotropy test.

vDigit Number of digits for reporting parameter estimates and standard errors. For

example, setting it to 1000 means printing out values up to three digits below

zero.

#### **Details**

pTest implements the hypothesis testing for pleiotropy. It requires two GPA model fits, one of interest and one under the null hypothesis (obtained by setting pleiotropyH0=TRUE when running GPA function), and evaluates genetical correlation among multiple phenotypes using the likelihood ratio test.

# Value

Returns a list with components:

pi pi estimates.

piSE Standard errors for pi estimates. statistics Statistics of the pleiotropy test. pvalue p-value of the pleiotropy test.

shinyGPA( out=NULL )
```

# Arguments

out

output of fitAll function.

#### **Details**

shinyGPA runs the ShinyGPA app. It takes the output of the fitAll function, which fits the GPA model for all possible pairs of GWAS datasets, as input.

# Value

Provides visualization to investigate pleiotropic architecture using GWAS results.

# Author(s)

Dongjun Chung, Emma Kortemeier

# References
